

WHAT?

A transparent machine Learning Model to achieve fairness in credit scoring.

WHY?

Traditional credit models can produce unfair outcomes, even without using protected attributes (ECOA & Credit Bureau) due to proxy variables and overweighted elements.

HOW?

- Thematic and data analysis of existing models
- Linear model (interpretability)

sponsored by

MODEL

$$S_i = b + \sum_j w_j x_{ij}^* + \sum_{(k,l) \in \mathcal{R}} g_{kl}(x_{ik}^*, x_{il}^*) + \sum_{(a,b,c) \in \mathcal{T}} h_{abc}(x_{ia}^*, x_{ib}^*, x_{ic}^*)$$

Relationship Type

- Compounding = risk compounds risk
- Buffering = one variable softens another
- Reinforcing = two stability signals reinforce
- Conditional = depends on context

+29% Approval Rate
without sacrificing performance

RESULTS

UNCERTAINTY

CONCLUSIONS

Model supports more inclusive lending, contributing to economic growth.
